Optical Properties of One-Dimensional Binary Plasma Dielectric Photonic Crystal

Bin Guo and Mingxiang Gao

Abstract—The optical properties of electromagnetic (EM) waves propagating in one-dimensional plasma dielectric photonic crystal made of alternate thin layers of two materials namely micro plasma layer and dielectric material layer is studied theoretically. The dispersions both for \( \omega < \omega_p \) and \( \omega > \omega_p \) are deduced by transfer matrix method and the photonic band gap structure and the reflection spectra are computed. The results show that the band gap structure and reflection spectra are tuned correspondingly due to the dielectric constant of the microplasma layer modified differently in different frequency ranges. Parameter dependence of the effects is calculated and discussed.

Index Terms—plasma; dispersion; photonic band structure; reflection spectra

I. INTRODUCTION

Photonic crystals (PCs) are composed of periodic dielectric or metal-dielectric nanostructures that affect the propagation of electromagnetic (EM) waves in the same way as the periodic potential in a semiconductor crystal affects the electron motion by defining allowed and forbidden electronic energy bands. Essentially, PCs contain regularly repeating internal regions of high and low dielectric constant. Photons (behaving as waves) propagate through the nanostructures depending - or not - depending on their wavelength. The wavelengths of light that are allowed to travel are known as modes, and the groups of allowed modes form bands. Disallowed bands of wavelengths are called photonic band gaps. Since the pioneering works of Yablonovitch [1] and John [2] on this field many new inquisitive ideas have been developed. The main attraction of the PCs is the existence of forbidden band gaps in their transmission spectra. To achieve suitable band gaps, there are great efforts to obtain tunability of band gaps [3-6]. Recently, a lot of studies on plasma photonic band gaps materials, which physics properties of dielectric constant, can vary continuously in space with the changes of frequency of incidence electromagnetic (EM) waves. The change in the physics properties makes the plasma photonic band gaps structure very different in behavior from the conventional composite materials. Now, these periodically plasma structure is known as plasma photonic crystal (PPC), which is presented by Hojo and Mase [7]. The technologies applications of PPC are now expanding widely as, for example, in plasma lens [8], plasma antenna [9], plasma stealth aircraft [10-13], etc. And the reflectionless transmission due to the Fabry-Perot resonance in PPC can be applied to frequency filters [14] and interferometers [15]. Moreover, PPC has not only the characteristics of photonic crystal, but also the characteristics of plasma. Therefore we can regulate the plasma parameters to achieve the regulation of PPC. Moreover, by replacing solid material with plasma, two important features are added to conventional PC: time-varying controllability and strong dispersion around the electron plasma density. These two features make the frequency of EM wave propagating in PPC range from microwaves to THz waves, according to the scale and the electron density of plasma [16].

PPC is spatially periodic distribution structure, including plasma and dielectric periodic placed, or PPC is plasma layer with period distribution density. Several researches have been analyzed both analytically and numerically. Kuo et al. [17] have studied the interaction of EM waves with rapidly created time-varying periodic plasma. Hojo Hitoshi et al. [7] discussed the dispersion of EM waves in one-dimension PPC using a method analogous to Kroning-Penny’s problem in quantum physics. Liu et al. [18, 19] have investigated the EM waves propagating process and reflection and transmission electric field of Gauss pulses passing the PPC. Laxmi et al. [20] have studied the photonic band gap effects in one-dimension plasma dielectric photonic crystal. O. Sakai et al. have studied two-dimension PPC both experimentally [21] and numerically [22].

In the presented communication, we have studied the dispersion and reflection properties of a multi-layered structure with microplasma materials slabs. It has been founded that the plasma parameters have marked influence on their photonic band gap structures and reflection spectra in optical region.

The structure of the paper is organized as follows. The model and corresponding analytical formulas, such as the dispersion relation and the reflection coefficient, are introduced in Sec. II. Numerical results are presented and discussed in Sec.III. Finally, conclusions are given in Sec. IV.

II. MODEL AND FORMULATIONS

The schematic diagram of the EM waves propagating in one-dimensional PPC is shown in Fig.1. We assume that the plasma dielectric photonic crystal is divided into a number of units and each unit has two medium which one is plasma materials with width \( a \) and the other is background material with width \( b \), and \( \Lambda = a + b \) is the width of unit sell. For this periodic structure, the dielectric function has the form as given by
The electric field $E(x)$ within each homogeneous layer is a combination of right-traveling waves and left-traveling waves and so it can be expressed as the sum of the incident wave and the reflected wave plane waves. Thus the solution of electric field $E(x)$ for the $n$th unit can be written as, for $\omega < \omega_p$

$$E(z) = \begin{cases} A_n e^{i k_n z} + \bar{A}_n e^{-i k_n z} & \text{if } \omega < \omega_p \\ B_n e^{i k_n z} + \bar{B}_n e^{-i k_n z} & \text{if } \omega > \omega_p \end{cases}$$

(3a)

and for $\omega > \omega_p$

$$E(z) = \begin{cases} A_n e^{-i k_n z} + \bar{A}_n e^{i k_n z} & \text{if } \omega < \omega_p \\ B_n e^{-i k_n z} + \bar{B}_n e^{i k_n z} & \text{if } \omega > \omega_p \end{cases}$$

(3b)

where

$$k_n = \sqrt{\frac{\omega^2}{c^2} - \varepsilon_n}^{1/2}, \quad k'_n = \left(\frac{\omega^2}{c^2} - \frac{\varepsilon'_n}{\varepsilon_n} \right)^{1/2},$$

and $A_n$, $\bar{A}_n$, $B_n$, and $\bar{B}_n$ are the amplitudes of counter propagation waves in different unit and $c$ is the speed of light in free space.

For obtaining the optical properties of the proposed structure we are using transfer matrix method. Therefore, the constants $A_n$, $\bar{A}_n$, $B_n$, and $\bar{B}_n$ are related with $2 \times 2$ matrix formulation for a period.

Then we look for the solution the matrix elements for two cases, $\omega < \omega_p$ and $\omega > \omega_p$.

Firstly, we impose the continuity conditions of $E_i$ and $H_i$ at the surface $z = (n-1) \Lambda$ and $z = (n-1) \Lambda + b$. We can obtain, for $\omega < \omega_p$

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} A_{n-1} \\ \bar{A}_{n-1} \end{pmatrix} = \begin{pmatrix} e^{i k_n \Lambda} \\ e^{-i k_n \Lambda} \end{pmatrix} \begin{pmatrix} B_n \\ \bar{B}_n \end{pmatrix}$$

(4a.1)

and for $\omega > \omega_p$

$$\begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \begin{pmatrix} A_{n-1} \\ \bar{A}_{n-1} \end{pmatrix} = \begin{pmatrix} e^{-i k_n \Lambda} \\ e^{i k_n \Lambda} \end{pmatrix} \begin{pmatrix} B_n \\ \bar{B}_n \end{pmatrix}$$

(4b.1)

From equations (4a) and (4b) eliminating $\bar{B}_n$, we can obtain

$$\begin{pmatrix} A_{n-1} \\ \bar{A}_{n-1} \end{pmatrix} = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix} \begin{pmatrix} A_n \\ \bar{A}_n \end{pmatrix}$$

(5)

where $\begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}$ is unite transfer matrix, and we can obtain the element of the matrix from equations (4a), (4b) and (5) with the condition $M_{11} M_{22} - M_{12} M_{21} = 1$. The matrix elements $M_{11}, M_{12}, M_{21}$ and $M_{22}$ are obtain as, for $\omega < \omega_p$

$$M_{11} = \cos k_n b + \frac{1}{2} \left( \frac{i k_n}{k_m} + \frac{k_m}{i k_n} \right) \sin k_n b e^{i k_m b}$$

(6a.1)

and for $\omega > \omega_p$

$$M_{11} = \cos k_n b + \frac{1}{2} \left( \frac{i k_n}{k_m} - \frac{k_m}{i k_n} \right) \sin k_n b e^{i k_m b}$$

(6b.1)

and

$$M_{21} = \cos k_n b + \frac{1}{2} \left( \frac{i k_n}{k_m} + \frac{k_m}{i k_n} \right) \sin k_n b e^{-i k_m b}$$

(6a.2)

and for $\omega > \omega_p$

$$M_{21} = \cos k_n b + \frac{1}{2} \left( \frac{i k_n}{k_m} - \frac{k_m}{i k_n} \right) \sin k_n b e^{-i k_m b}$$

(6b.2)

Then, from the periodicity of $\varepsilon(x)$ shown by equation (1) and also of given by $E(x) = E(x + \Lambda)$, and using the Floquet theorem [23], we can obtain that the phase coefficient $e^{i k \Lambda}$ is the eigenvalue of the eigenequation which can be
described as below
\[
\begin{pmatrix}
M_{11} - e^{-i\omega \Lambda} & M_{12} \\
M_{21} & M_{22} - e^{-i\omega \Lambda}
\end{pmatrix} = 0
\]  \hspace{1cm} (7)

Here, \( K \) is known as Bloch wave number and is a function of \( \omega \). Then the dispersion relation can be obtained from the equation (6), as written by
\[
K(\omega) = \frac{1}{\Lambda} \cos^{-1} \left[ \frac{1}{2} \left( M_{11} + M_{22} \right) \right]
\]  \hspace{1cm} (8)

Substituting equations (6a) and (6b) in equation (8), we can obtain the dispersion relation of P-polarization electromagnetic waves propagation in one-dimension plasma dielectric photonic crystal, for \( \omega < \omega_p \),
\[
\cos \Lambda a = \cos k_\omega a \cos k_\omega b + \frac{1}{2} \left( \frac{k_{\omega a}}{k_\omega} - \frac{k_{\omega b}}{k_\omega} \right) \sinh k_\omega a \sinh k_\omega b
\]  \hspace{1cm} (9a)

and for \( \omega > \omega_p \),
\[
\cos \Lambda a = \cos k_\omega' a \cos k_\omega' b - \frac{1}{2} \left( \frac{k_{\omega a}}{k_\omega} + \frac{k_{\omega b}}{k_\omega} \right) \sinh k_\omega' a \sinh k_\omega' b
\]  \hspace{1cm} (9b)

The reflection coefficient of such considered periodic structure for \( N \) number of period can be obtained by using Eqs.(4). The reflection \( r_N \) = \( \left( \frac{A}{A'} \right) \) when the reflection by \( N \)th layer is zero. So, the reflectance of the proposed structure for \( N \) number of period is given by [24]
\[
R = \left| r_N \right|^2 = \frac{\left| M_{21} \right|^2}{\left| M_{22} \right|^2 + \sin \left( K \Lambda \right) \sin \left( N K \Lambda \right)}
\]  \hspace{1cm} (10)

So, we can use the Eqs.(9) and (10) to obtain and discuss the dispersion and reflection of the proposed structure.

III. RESULTS AND DISCUSSION

To evaluate the optical properties, band gap structure and reflectance, of the proposed multi-layered we used the Eqs. (9) and (10). We note that there are there selective parameters, \( \omega_p/2\pi c \) (For simplicity, we introduce the dimensions variable \( \omega_p/2\pi c \) which is normalized to 1 at \( \omega = \omega_p \)), plasma filling factor \( f \) (which is expressed as \( f = a/\Lambda \)), and the dielectric constant value \( \varepsilon_b \) which is normalized to \( \varepsilon_b/\varepsilon_0 \) in the numerical calculations.

Firstly the dispersion relation for \( \omega_p/2\pi c = 1, \varepsilon_b = 1 \) (for air), \( f = 0.1 \) and \( f = 0.3 \) is shown in Fig. 2, of which (a) depicts

The dispersion relation of \( \omega < \omega_p \) and (b) does the one of \( \omega > \omega_p \). It can be seen that the dispersion relation becomes a band structure with frequency with frequency gaps, and there is a cut-off frequency. It is clear that the frequency band gap becomes larger with the increase in plasma filling factor. Fig. 3 shows the reflection spectra versus the frequency of incident EM wave. Here we have taken the number of periods, \( N = 4 \), which is fixed in the numerical calculation. Other parameters are as the same as above. From Fig.3, we can easily conclude that the photonic band gap is getting larger with an increase in the plasma filling factor. The gap region shifts towards the higher frequency with the increase in plasma filling factor.

Next the dispersion relation for \( \omega_p/2\pi c = 1, f = 0.1, \varepsilon_b = 1 \) (for air), and \( \varepsilon_b = 2 \) (for SiO2) is shown in Fig 4, where the
frequency band gap is smaller for the larger dielectric constant value $\varepsilon_b$ of background material or increasing the background material dielectric constant value $\varepsilon_b$ leads to the creation of new photonic band gaps and to flattening of the photonic band gaps which means the reduction of group velocity. Fig. 5 shows the reflection spectra versus the frequency of incident EM wave. It is obvious from Fig. 5 that the number of frequency band gap becomes larger and the frequency band gap gets flatter and deeper appreciably increasing the background material dielectric constant $\varepsilon_b$. At the same time, the frequency bandwidths will be broadened and the space between the photonic band gaps will be reduced. Comparing with the Fig.2 and Fig.3 or Fig.4 and Fig.5, there are highly consistent with each other for depiction of the photonic band gap.

IV. CONCLUSION

In summary, we have deduced the dispersion relations of EM wave propagation in one dimensional multi-layered structures containing plasma material both for $\omega < \omega_p$ and $\omega > \omega_p$ exclusively. The graph for dispersion relations and the reflection spectra is computed and plotted. The effects of plasma parameters such as plasma filling factor and the background material dielectric constant value are discussed. The results show that the proposed multi-layered structure can be acted as a tunable photonic crystal which can be controlled by the external parameters. Comparing with conventional photonic crystal, the multi-layered structure containing plasma material, as an innovative and dynamic field, will bring more new physics phenomena, draw more attention and lead to many new applications in the future.
